Globicus Leading Economic Index

Outlook January 2023

Leading Economic Index:
We Are Headed for A Recession

Globicus Inc.

New York

December 27, 2022

Table of Contents

1. Executive Summary

Globicus Leading Economic Indexes were all negative in the latest reading in December, suggesting that a US recession may start in the first quarter 2023 and may be deeper than most people expect. The model has an excellent historical record having predicted all recessions since the 1960s except the Covid 19 "recession" 2020, which was primarily the result of the shutdown of the economy. The coincident index showed continued growth although at slower pace in November.

With continued high inflation, the Fed is unlikely to reverse course. The "market" has reluctantly followed the Fed's lead but is still not buying the Fed's continuously hawkish signals.

Inflation is a lagging indicator and does not usually decline until unemployment rises and/or the economy enters a recession. The historic experience is that higher unemployment is necessary to reduce inflation. This makes it exceedingly difficult for the FOMC to tighten appropriately to reduce inflation while at the same time avoiding a recession. Additionally, during periods with high historical inflation the Fed mostly continued to keep interest rates high at the beginning of the recessionary period.

2. GLEI Indexes Declined in November

Globicus Leading Economic Indexes (Total- Long- and Short leading index)[1] all had negative readings for November, indicating an impending recession. The coincident Index (designed to coincide or measure the overall economy, i.e., the business cycle) is moderating from strong numbers earlier this year but showed still relatively strong growth in November.

Globicus Leading Economic Indexes

Source: National sources and Globicus calculations
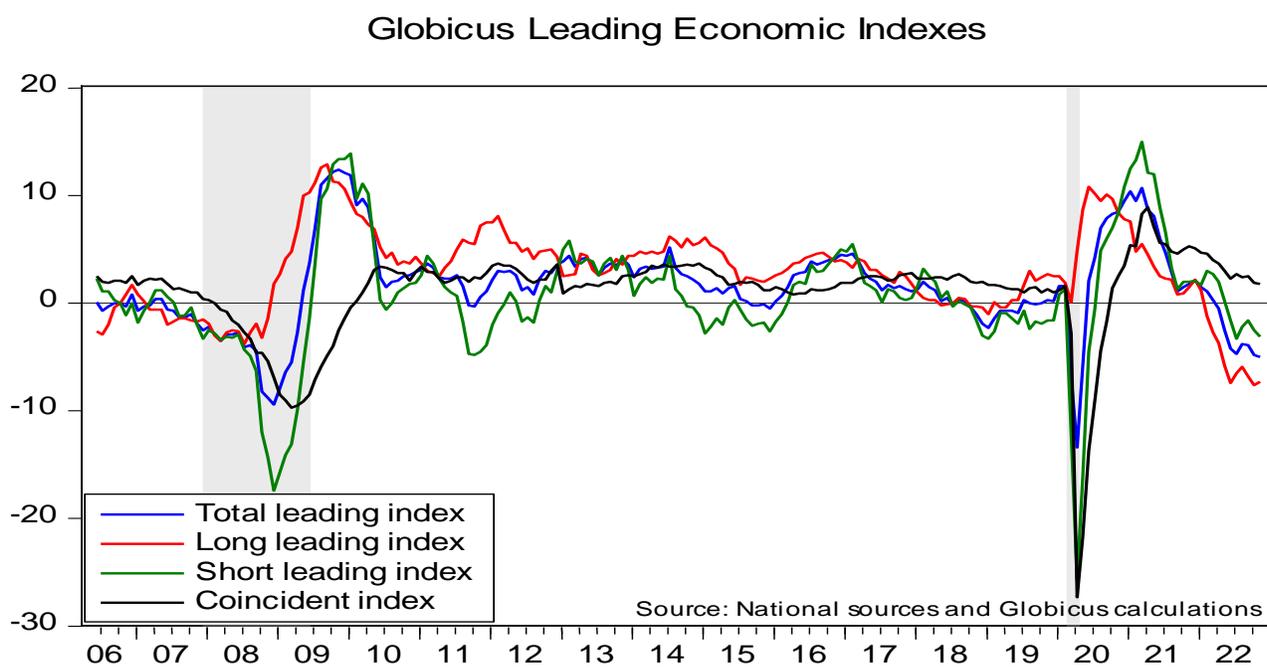

The total leading index's Six-month Smoothed Growth Rate ("SMGR")[2] fell in November to -5.1 from -4.9 in October, the eighth consecutive monthly negative

---

[1] We are using three leading indexes. The reason for this is that leading indicators have different lead time, and it can be useful to disaggregate what the long and short leading indexes indicates. The total leading index is a combination of the short and the long leading index and is constructed to smooth out the volatility of the individual indexes and to get a timely indication.

[2] For input series X the formula for six-month smoothed growth rate is: Xsmgr= (X(t)/Avg of previous 12 months)^(12/6.5)-1

reading, new and revised data showed. The long leading index rose to -7.4 in November from -7.7 in October, its tenth negative reading. The short leading index recorded its sixth negative reading, declining to -3.2 in November from -2.6 in October.

The coincident index, a measure of the current economic activity, slipped to 1.7 SMGR in November from 1.8 the previous month. Although still relatively strong, the coincident index has slowed significantly from the 5.6 SMGR a year earlier.

Overall, economic weakness will intensify and spread more broadly throughout the US economy over the coming months with a recession to start in the beginning of 2023.

3. Yield Curves Sharply Negative in December

Inverted yield curves usually precede a recession, particularly the spread between 10-year and the 3-month treasury securities normally turns negative just before a recession. This spread has narrowed dramatically since the Fed got religion and just turned negative on October 25. This spread has been between 60-90 basis points negative so far in December. The 10year–2year spread generally tightens before the 10y/3m spread and has been negative since July and has been tracking the 10y/3m spread in December. We prefer the 10y/3m spread as it is more timely and better capture Fed's policy. This spread typically turn from negative to positive before the recession starts and have always done so since the 1990 recession. However, that was not the case during the four recessions in the 1970 to 1982 period. These four recessions were all preceded by high inflation in contrast to the following recessions that were accompanied by more modest inflation. Therefore,

we may not see a reversal of the negative spread before the recession starts as the high inflation rate today is more reminiscent of the high inflation recessions during the seventies and eighties rather than the more recent lower inflation recessions.

### Yield Curve Inversion and Inflation

5
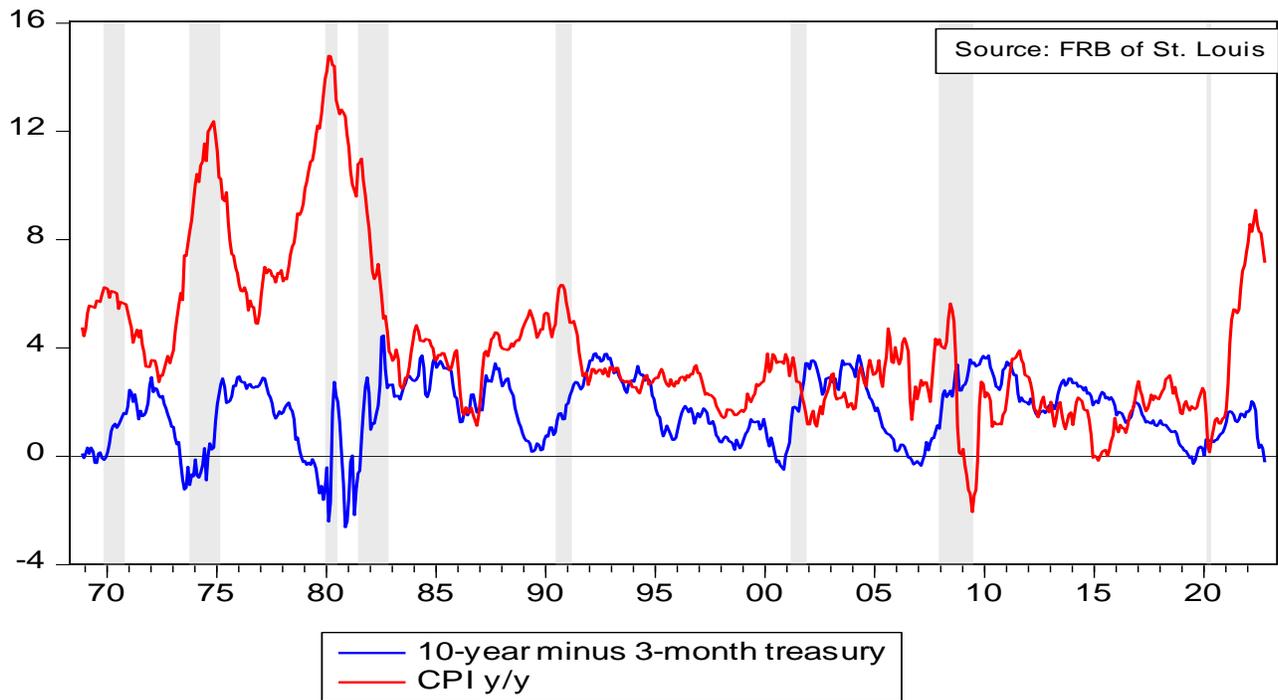

4. Fed was Late but is Now Committed

With the highest inflation rate in four decades, it is unlikely that the Fed will back down from its planned rate hikes and quantitative tightening before they see convincing signs of price stability. The FOMC increased, as expected, the federal funds range 50bp to 4.25%-4.50% at its December meeting. It also announced a continuation of its balance sheet reduction. The Fed said that "recent indicators point to modest growth in spending and production. Job gains have been robust in recent months, and the unemployment rate has remained low. Inflation remains elevated, reflecting supply and demand imbalances related to the pandemic, higher food and energy prices, and broader price pressures." According to Fed's Summary of Economic Projections, December 14, 2022.[3] The Fed expects GDP growth at 0.5%, unemployment at 4.6%, PCE inflation at 3.1% and fed funds rate at 5.1% in 2023. The so-called dot-plot, which shows FOMC participants' assessment of appropriate monetary policy, i.e., the mid target level for the federal funds rate at the end of 2023. Ten participants predicted federal funds rate between 5.0%-5.25%, five participants between 5.25%-5.50% and two participants between 5.50%- 5.75% at the end of 2023.

5. Unemployment and Recession Cure Inflation

From the chart below, we can see that there is a substantial lag from when the Fed starts increasing the Fed funds rate to when the unemployment rate increases. Not until the unemployment rate increases significantly does inflation fall. To address the Inflation problem unemployment usually needs to increase and economic activity fall. In the previous seven recessions[4], going back to 1970, unemployment rose on average 2.6 percentage points. If this pattern is repeated, unemployment could peak at 6.3%.

Fed Funds Rate vs Unemployment Rate
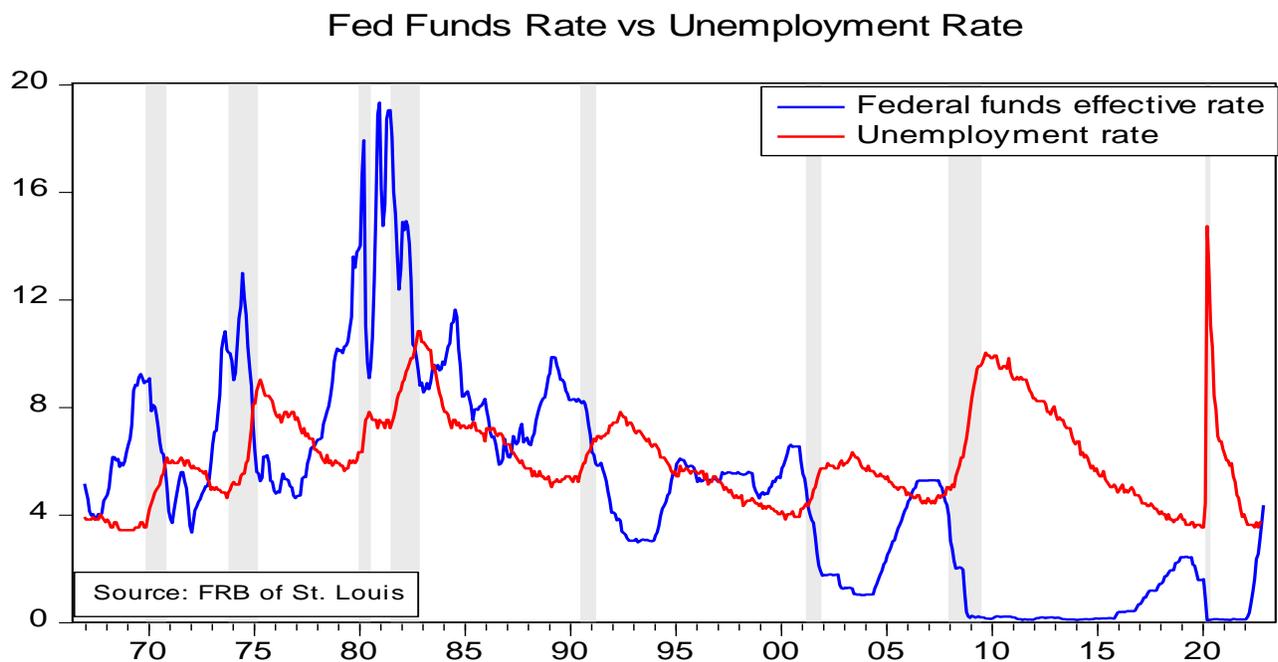

[4] This does not include the Covid recession 2020.

The rise in unemployment rate, which historically defines the recession[5], is what finally brings down inflation. When unemployment start rising it is normally some time before inflation falls and inflation does not fall significantly until recession starts.

Unemployment Brings Down Inflation

Source: FRB of St. Louis

The Sahm Rule[6] identifies signals related to the start of a recession when the three-month moving average of the unemployment rate rises by 0.5% or more from its low during the previous 12 months. This is not a leading indicator but coincides with recessions and as you can see it indicates no recession as unemployment has not risen yet.

Sahm Rule: Unemployment and Recession

Source: FRB of St. Louis
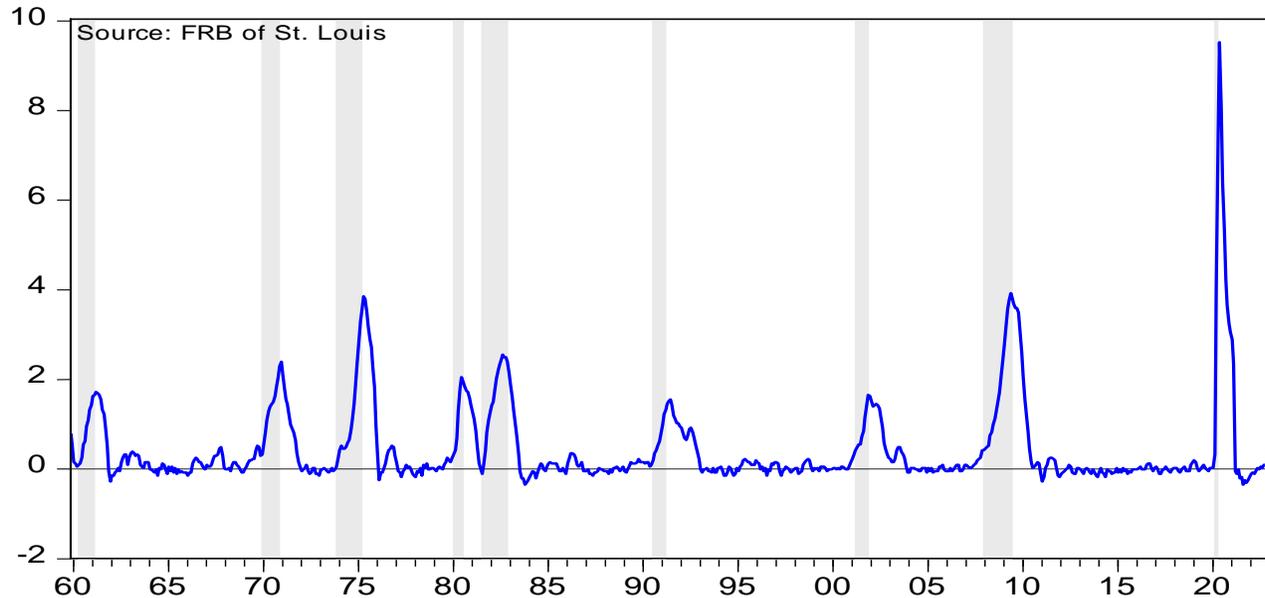

Inflation has moderated from its recent peak of 9.1% in June to 7.1% in November, measured by CPI. The improvement stems mostly from the opening of supply chains and other bottlenecks. Primarily the relief is in the goods market, while service inflation and wage pressure continue to be high. The Fed have emphasized that they will not change their tune until inflation is back to 2.0% which is unlikely to happen until there is significant increase in unemployment.

6. Fed is Still Behind the Curve

Before the 2001 recession the Fed's policy rate, the federal funds rate (FFR) was mostly above the inflation rate and since the Great Recession 2008 fed funds rate was mostly well below the inflation rate. The exceptions to the negative rate were in the 2006-2007 before the Great Recession and a few months in 2019 before the Covid 19 recession.

Inflation and The Fed's Policy Rate

Source: FRB of St. Louis
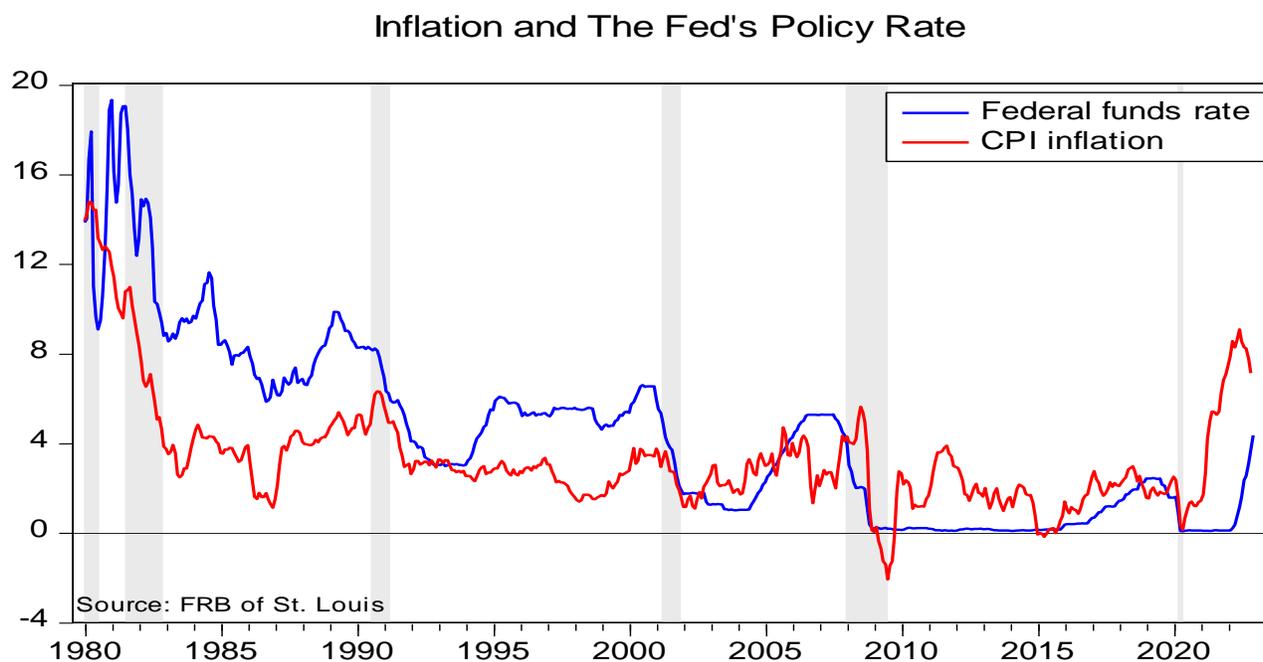

During the pandemic, the spread between inflation and fed funds rate widened to extreme levels. And despite the Fed's aggressive tightening by 400 basis points since March, the fed funds rate is still below the inflation rate. The Fed has signaled 50 basis points rate hike at their February 1 meeting. The market doesn't believe the Fed and have only discounted a 25 bp hike. We believe the Fed will hike 50 bp in February. However, if the unemployment rate increase meaningfully and the recession start in the beginning of 2023, it may be the last increase in fed funds rate. On the other hand, the Fed has indicated that it will not pivot until the inflation is back to its target. Should, the Fed's action during the high inflation experience in the seventies and eighties be any guide, we should believe them. And they may continue raising rates even as unemployment increases.

Many economists believe that to cure inflation the real rate needs to be positive. One can debate what the real rate is. Here we use FFR deflated by University of Michigan's inflationary expectations. Real FFR has been negative since the Great Recession. And following the pandemic rates fell to new all-time lows. The real FFR has recovered from -5.2% in March to -0.3 in December following Fed's aggressive tightening.

Real Fed Funds Rate
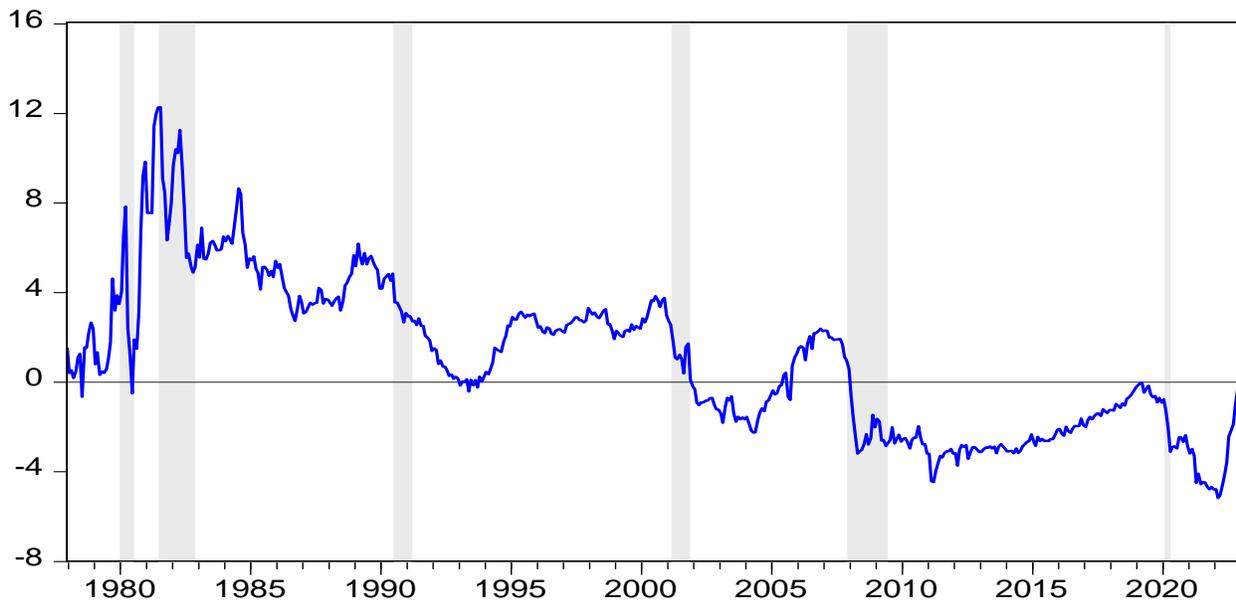

The FRB of Cleveland has a one-year real interest rate estimate. This measure turned positive in October and had a real yield of 0.77% in December.[7]

---

[7] The Federal Reserve Bank of Cleveland estimates the expected rate of inflation over the next 30 years along with the inflation risk premium, the real risk premium, and the real interest rate. Their estimates are calculated with a model that uses Treasury yields, inflation data, inflation swaps, and survey-based measures of inflation expectations.

1-Year Real Interest Rate
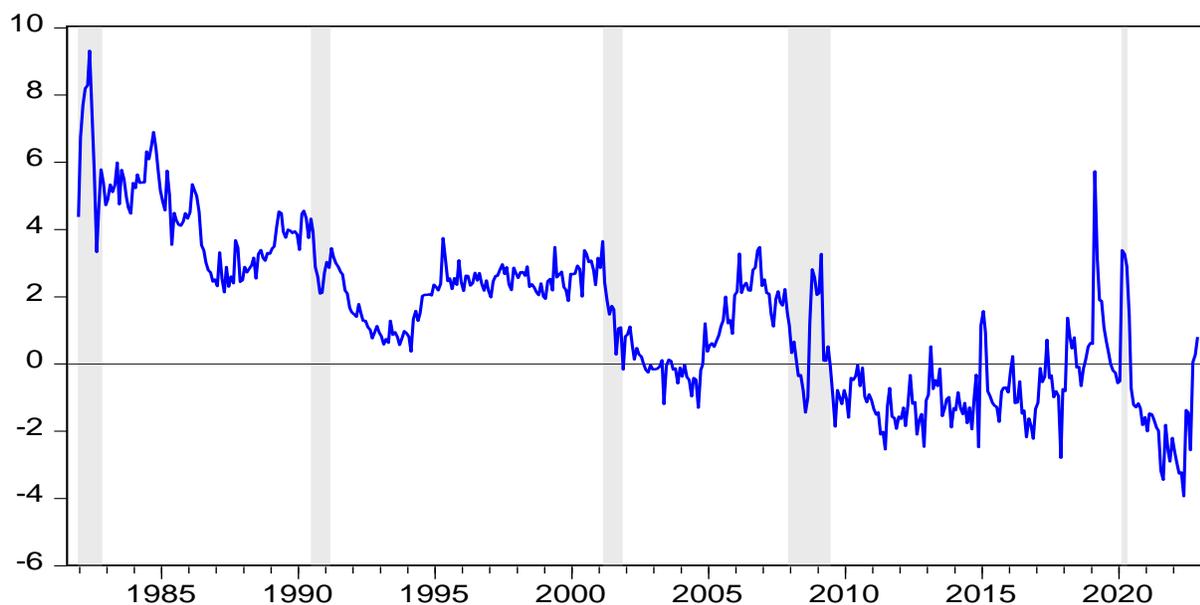

We do not believe in immaculate disinflation policies, the idea that we can get easing price pressure without significant economic and labor market slack. However, it is possible, even likely, that easing commodity prices and transitory effects will reduce inflation a few percentage points. However, the difficult part will be returning inflation to the Fed's stated goal of 2% from say 4% or 5%, without higher unemployment.

7. The Recession Develops Slowly

Below are the model's results since 1970. The blue line is the model's total leading growth rate, designed to forecast economic activity and recessions. The red line is the coincident index, designed to measure current economic activity. How reliable in the model? We have high confidence in the recession prediction. The model has

predicted all recessions since the 1970s. However, exact timing of the start of a recession is more of a challenge. When the total leading index turns negative it precedes a recession on average by 9 months. However, these leads vary. The total index turned negative in April, so the recession could start in December or January. The strong labor market may postpone the recession. 10-year/3month yield spread turns negative several months before the recession and since the 90s turns positive again before the recession starts. However, this was not the case in earlier recessions when inflation was as high as it today. Therefore, we may not see a reversal in the spread before the recession starts.

The great economist Rudi Dornbusch once said, "the crisis takes a much longer time coming than you think, and then it happens much faster than you would have thought."[8] We are convinced that the recession will come but the timing is uncertain. Therefore, we conclude that there will be a recession and it will probably start the in the first quarter 2023.

Globicus Leading and Coincident Indexes
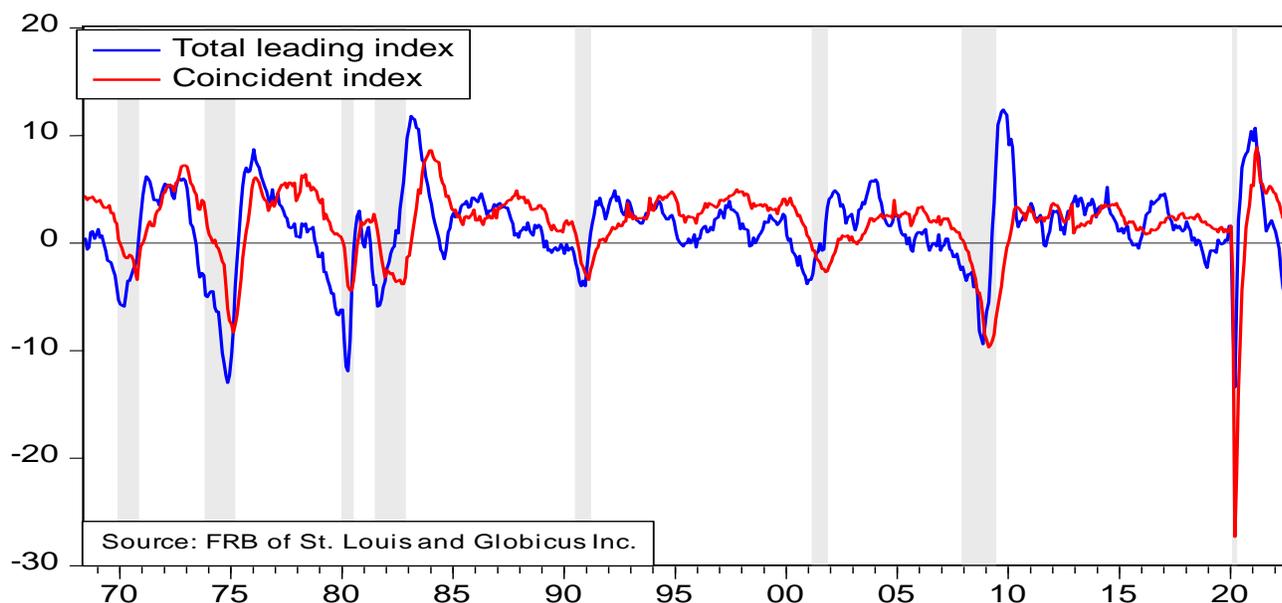

There isn't, as far as we know, any reliable way to forecast the depth of a recession. Still, many forecasters predicting a recession, also predict a shallow recession because of a strong labor market, over-sized pandemic savings and no major imbalances. There has been a long time with very low interest rates, and imbalance may not show up until the recession is upon us. We believe that one can get a rough idea of the depth of the recession from the depth of the decline in the leading indicators. In November the total leadinng indicator stood at -5.1. This is the lowest reading, before a recession has been observed, exept for the reading of this index before the onset of the 1980 recession. Currently the total leading index is lower than the lowest point during the 1990 recession and the 2001 recession. The total leading index generally falls further during the earlier parts of the recession. At -5.1, the total leading index is similar to the reading for the 2008 recession and the four high inflation recessions in the seventies and early eighties. During these five recessions unemployment rate rose on average 2.8 percentage points and the downturn lasted on average 14 months. During the 1990 and 2001 moderate inflation recessions, the average unemployment rate

15

increased 1.25 percentage points and the downturn lasted only 7 months. This is less than half compared to the other recessions when the total leading index declined significantly. Therefore, we don't believe this recession will be shallow.
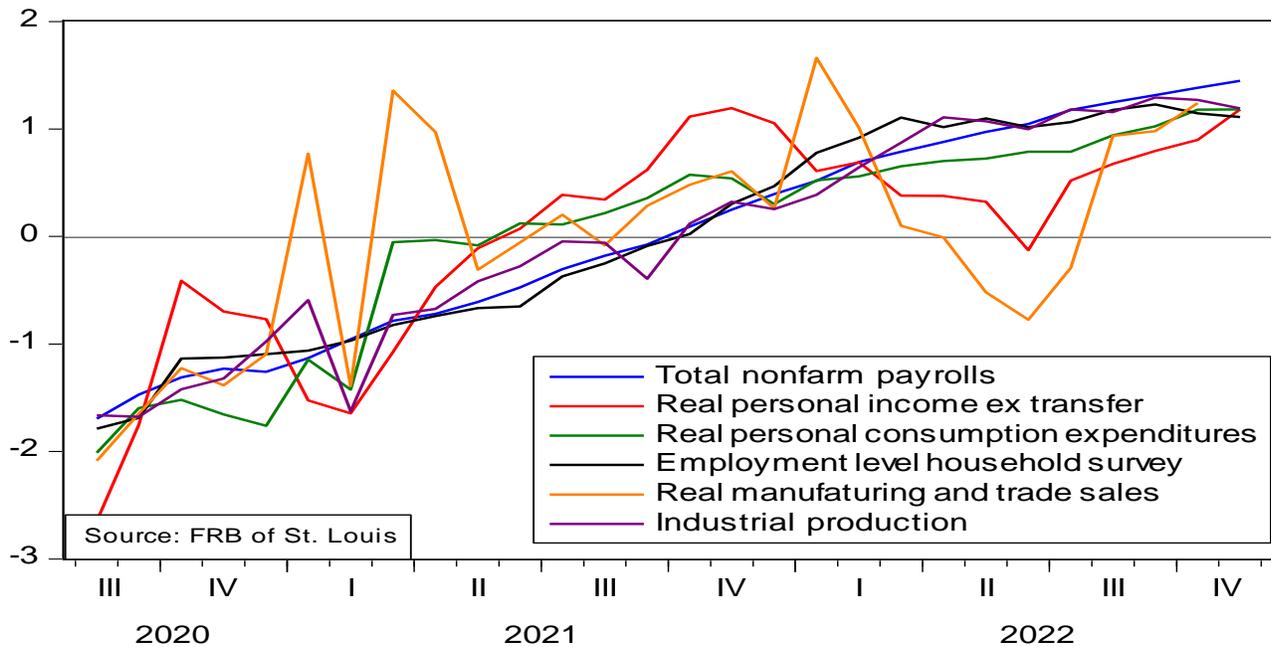

8. The US Economy Is Still Expanding

NBER's Business Cycle Dating Committee maintains a chronology of the US business cycles. The committee's definition of a recession is "a significant decline in economic activity that is spread across the economy and that lasts more than a few months."[9]

The committee's determination of the months of peaks and troughs is based on a range of monthly measures of aggregate real economic activity. These include real personal income less transfers, nonfarm payroll employment, employment as measured by the household survey, real personal consumption expenditures, wholesale-retail sales adjusted for price changes, and industrial production. In addition to the monthly indicators, they use two quarterly indicators, gross domestic income (GDP) and gross domestic income (GDI). GDP rose 3.2% in the third quarter and GDI rose 0.8% both at compounded annual rate of change.

The monthly indicators the Dating Committee uses are shown in the graph below and does not seem to show any significant and widespread decline. They look like they are mostly growing as of their latest reading which are for October and November. These coincident indicators are not showing any widespread slowdown. The only indicators that are not at recent highs are the employment level from the household survey and industrial productions which show modest declines.

- Real manufaturing and trade sales
- Industrial production

9. Conclusions

In summary, the total leading index suggests that the recession will start in the first quarter of 2023 as the strength in the labor market and the coincident index are still strong. The Fed's tightening cycle is unlikely to reduce inflation until unemployment rises significantly and that does not normally happen until the economy enter a recession. The Fed is still behind the curve and likely to push fed funds rate to 5.0%-5.25% unless the recession will change the FOMC's policy function.

From Globicus' coincident index and the Dating Committee's data used to track recessions it is unlikely that the economy is in a recession now. Or for that matter that the economy was in a recession in the first half of 2022, despite two consecutive quarters of negative growth in the first half of 2022.

Appendix A.

The Leading Index Approach

Macroeconomic forecasts attempt to provide useful information on aggregate economic conditions. When it succeeds it can provide clients with specific information that allows him or her to make better decisions.

One approach to forecasting is to construct a theoretical model, build an econometric model around it and identifying economic relationships, and then use the model to forecast economic activity. A different approach to economic forecasting involves using explicit statistical model that requires little economic theory. Examples of this atheoretical approach are vector autoregressive (VAR) models, ARIMA models and the leading index approach. The leading economic index approach, unlike standard economic models, is not to primarily predict the magnitude of future economic growth, but rather to recognize and predict major turning points for the economy.

The leading index approach was originated in the mid-1930s by Arthur F. Burns & Wesley C. Mitchell associated with the National Bureau of Economic Research (NBER)[10]. Their research explored cyclical patterns of economic fluctuations that consist of expansions followed by recessions which then merge into the expansion phase of the next cycle. Leading indicators are series that tend to change direction in advance of the business cycle and lead the overall economy. Coincident indicators are the series that coincide and move in sync with the overall aggregate economy. A coincident economic index should turn at the same time as the general economy and rise and fall at a similar pace as the overall economy. A leading economic index should decline before recessions, increase before a recovery, and forecast change in the overall economy's pace.

The leading index approach is designed to predict the direction of the economy in future months by predicting turning points in economic activity. For that purpose, indexes are developed from economic variables that leads the general economic activity. To better determine the turning points, we use six-month smoothed growth rate as it better represent turning points than regular moving averages.
